LED Drivers for LCD Backlights

White Backlight LED Driver
for Medium to Large LCD Panels
(Switching Regulator Type)

BD6142AMUV

● Description
This IC is white LED driver IC with PWM step-up DC/DC converter that can boost max 41V and current driver that can drive max 30mA. The wide and precision brightness can be controlled by external PWM pulse. This IC has very accurate current drivers, and it has few current errors between each strings. So, it will be helpful to reduce brightness spots on the LCD panel. Small package is suited for saving space.

● Features
1) High efficiency PWM step-up DC/DC converter (fsw=typ 1.25MHz, 0.60MHz ~ 1.6MHz)
2) High accuracy & good matching current drivers 8ch (MAX30mA/ch)
3) Integrated 50V power Nch MOSFET
4) Soft Start function
5) Drive up to 11 LEDs in series, 8 strings in parallel
6) Wide input voltage range (4.2V ~ 27V)
7) Rich safety functions
   • Over-voltage protection
   • External SBD open detect / Output Short protection
   • Over current limit
   • CH Terminal open / GND short protect
   • CH over voltage protect / LED short protect
   • thermal shutdown
   • UVLO
8) Analog Brightness Control
9) Small & thin package (VQFN024V4040) 4.0 × 4.0 × 1.0mm

● Applications
All medium sized LCD equipments, Backlight of Notebook PC, net book, monitor, light, Portable DVD player, light source etc.

Application example

Fig. 8, Fig. 9 and Fig. 10 are Application examples (15.4inch and 12inch and 10.1inch model). Recommended schematics and Layout are shown in Page. 21.
Fig. 10  BD6142A Application example (3 parallel)
Functional descriptions

1) PWM current mode DC/DC converter
While this IC is power ON, the lowest voltage of CH1, 2, 3, 4, 5, 6, 7, 8 is detected, PWM duty is decided to be 0.8V and output voltage is kept invariably. As for the inputs of the PWM comparator as the feature of the PWM current mode, one is overlapped with error components from the error amplifier, and the other is overlapped with a current sense signal that controls the inductor current into Slope waveform to prevent sub harmonic oscillation. This output controls internal Nch Tr via the RS latch. In the period where internal Nch Tr gate is ON, energy is accumulated in the external inductor, and in the period where internal Nch Tr gate is OFF; energy is transferred to the output capacitor via external SBD. This IC has many safety functions, and their detection signals stop switching operation at once.

2) Pulse skip control
This IC regulates the output voltage using an improved pulse-skip. In "pulse-skip" mode the error amplifier disables "switching" of the power stages when it detects low output voltage and high input voltage. The oscillator halts and the controller skip switching cycles. The error amplifier reactivates the oscillator and starts switching of the power stages again when this IC detects low input voltage.
At light loads a conventional “pulse-skip” regulation mode is used. The “pulse-skip” regulation minimizes the operating current because this IC does not switch continuously and hence the losses of the switching are reduced. When the error amplifier disables "switching", the load is also isolated from the input. This improved “pulse-skip” control is also referred to as active-cycle control.

3) Soft start
This IC has soft start function.
The soft start function prevents large coil current.
Rush current at turning on is prevented by the soft start function.
After Enable, PWM is changed 'L' → 'H', and UVLO is detected, soft start becomes effective for within typ 4.3ms and soft start doesn't become effective even if Enable is changed 'L' → 'H' after that.

4) FAULT
When the error condition occurs, boost operating is stopped by the protection function, and the error condition is outputted from FAULT. After power ON, when the protection function is operating about 4.3ms(typ.) have passed.
Once enable change to 'L', FAULT status is reset
Object of protect function is as shown below.
- Over-voltage protection (OVP)
- Thermal shut down (OTP)
- Over current limit (OCP)
- Output short protect
- LED Short (Latch)
- LED Open (Latch)

<td></td>
</tr>
</tbody>
</table>

- Over voltage protection (OVP)
  
  At such an error of output open as the output DC/DC and the LED is not connected to IC, the DC/DC will boost too much and the OVP terminal exceed the absolute maximum ratings, and may destruct the IC. Therefore, when OVP terminal becomes sensing voltage or higher, the over voltage limit protection works, and turns off the switching Tr, and DC/DC will be stopped.
  
  At this moment, the IC changes from activation into non-activation, and the output voltage goes down slowly. And, when the Feedback of CH1 isn’t returned, so that VOUT will return normal voltage.

---

Fig. 14 OVP operating description
This section is especially mentioned here because the spec shown electrical characteristic is necessary to explain this section.

Over voltage limit
- min 1.16V  typ 1.20V  max 1.24V
LED control voltage
- min 0.64V  typ 0.80V  max 0.96V
LED terminal over voltage protect
- min 4.25V  typ 5.00V  max 5.75V

1. Calculate the conditions that the total value of LED VF is MAX.
   Example) In the case of serial 8 LEDs with VF=2.9V(min), 3.2V(typ), 3.5V(max) => 3.5V x 8=28V

2. Then calculate the biggest value of output with the following formula.
   The biggest value of output = the biggest value calculated for 1 + the biggest value of LED terminal voltage. (0.96V)
   Example) The biggest value of output = 28V + 0.96V = 28.96V

3. Set the smallest value of over voltage larger than the biggest value of output.
   If over voltage is closer to the total value of VF, it could be occurred to detect over voltage by ripple, noise, and so on.
   It is recommended that some margins should be left on the difference between over voltage and the total value of VF.
   This time around 6% margin is placed.
   Example) Against the biggest value of output = 28.96V, the smallest value of over voltage = 28.96V x 1.06 = 30.70V
     \(I_{OV}\) over voltage limit
     - min=1.16V, typ=1.20V, max=1.24V
     typ = 30.70V x (1.20V/1.16V) = 31.76V
     max = 31.76V x (1.26V/1.20V) = 33.35V

4. The below shows how to control resistor setting over voltage
   Please fix resistor high between OVP terminal and output and then set over voltage after changing resistor between OVP terminal and GND. While PWM is off, output voltage decreases by minimizing this resistor. Due to the decrease of output voltage, ripple of output voltage increases, and singing of output condenser also becomes bigger.
   Example) Selecting OVP resistor.

   • OVP resistor selection
   (Example. 1) VF=3.5V max, serial = 7 LED
     \(OVP = 1.2V, R1 = 2.2M\Omega, R2 = 95.3k\Omega\)
     \(VOUT = 1.2 \times (2.2M\Omega + 95.3k\Omega)/95.3k\Omega = 28.90V\)
   (Example. 2) VF=3.5V max, serial = 8 LED
     \(OVP = 1.2V, R1 = 2.2M\Omega, R2 = 82k\Omega\)
     \(VOUT = 1.2 \times (2.2M\Omega + 82k\Omega)/82k\Omega = 33.40V\)
   (Example. 3) VF=3.5V max, serial = 9 LED
     \(OVP = 1.2V, R1 = 2.2M\Omega, R2 = 73.2k\Omega\)
     \(VOUT = 1.2 \times (2.2M\Omega + 73.2k\Omega)/73.2k\Omega = 37.27V\)
   (Example. 4) VF=3.5V max, serial = 10 LED
     \(OVP = 1.2V, R1 = 2.2M\Omega, R2 = 68k\Omega\)
     \(VOUT = 1.2 \times (2.2M\Omega + 68k\Omega)/68k\Omega = 40.02V\)

   • External SBD open detect / Output Short protection
   In the case of external SBD is not connected to IC, or VOUT is shorted to GND, the coil or internal Tr may be destructed.
   Therefore, at such an error as OVP becoming 50mV(typ.) or below, turns off the output Tr, and prevents the coil and the IC from being destructed.
   And the IC changes from activation into non-activation, and current does not flow to the coil (0mA).

   • Thermal shut down
   This IC has thermal shut down function.
   The thermal shut down works at 130°C (typ.) or higher, and the IC changes from activation into non-activation.
● Operating of the application deficiency

1) When 1 LED or 1 string OPEN during the operating
The LED string which became OPEN isn't lighting, but other LED strings are lighting. Then LED terminal is 0V, output boosts up to the over voltage protection voltage. When over voltage is detected, the feedback of open string isn't returned, so that VOUT will return normal voltage.

2) When LED short-circuited in the plural
All LED strings are turned on unless CH1~8 terminal voltage is more than 5V (typ.). When it was more than 5V only the strings which short-circuited is turned off normally and LED current of other lines continue to turn on. Short line (CH1) current is changed from 20mA to 0.05mA (typ), so CH1 terminal don't heat.

3) When Schottky diode remove
All LED strings aren't turned on. Also, IC and a switching transistor aren't destroyed because boost operating stops by the Schottky diode open protected function.
● Control Signal input timing

Timing sequence 1
Referring to Fig. 17, the recommended turn “on” sequence is VIN followed by ENABLE and PWM. The recommended turn “off” sequence is ENABLE and PWM followed by VIN. This sequence is recommendation.

Min 0μs

2 ~ 5V

0 ~ 0.8V

*other signal is input after a signal turned off.

*other signal is input after a signal turned on.

*Other signal is input after a signal turned off.
Timing sequence
Referring to Fig.19, the recommended turn “on” sequence is VIN, PWM followed by ENABLE. The recommended turn “off” sequence is ENABLE followed by PWM and VIN.

**VIN wake up speed**

In case, there is PWM OFF status (min: 10ms) during operation as Fig. 21, ENABLE should turn from ‘H’ to ‘L’ as Fig.21. If PWM stops and VOUT voltage is dropped, this IC will be condition of current limiter when PWM starts (no soft start). If soft start isn’t needed, reset is no need.
How to activate
Please be careful about the following when being activated.
- Regulator (VDC) operates after ENABLE=H. Inside circuit operates after releasing UVLO. When IC boosts after releasing UVLO, soft start function operates. (Refer to Fig.12, 7th page). Soft start circuit needs $t_{15}$ (more than 15µs) as Fig. 22 shows. Soft start operates for $T_{soft}$ time. Please make H width of PWM more than 15µs until soft start finishes.
- Please input PWM signal according to Fig. 23 after soft start finishes.

Example) Time until soft start finishes at PWM frequency 25kHz and PWM=H time16µs
According to soft start time typ4.3ms
$t_{soft} = 16µs - 15µs = 1µs$
Soft start time/ $t_{soft}$/PWM frequency = 4300µs / 1µs /25kHz = 4300 / 25kHz = 172ms

At light dimming of PWM terminal (after soft start finishes)
How to select the number of LED strings of the current driver

When the number of LED strings of the current driver is reduced, the un-select can be set the matter that the unnecessary CH1 ~ 8 terminal is opened. When it uses with 6 lines and so on, it can correspond to it by becoming 2 unnecessary lines to open.

When VOUT wake up, VOUT boost up until OVP voltage. Once IC detect OVP, VOUT don’t boost up until OVP from next start up. To set PWM and Enable to L, IC reset CH7, 8 status as Fig. 24. When VOUT wake up, CH8 (open terminal) and CH1 are selected as Fig. 25.

![Diagram](image_url)

Fig. 24 Select the number of CH lines 1

![Diagram](image_url)

Fig. 25 Select the number of CH lines 2 (wake up)
Start control (Enable) and select LED current driver (PWM)
This IC can control the IC system by Enable, and IC can power off compulsory by setting 0.8V or below. Also, It powers on Enable is at more than 2.0V.
After it’s selected to Enable=H, When it is selected at PWM=H, LED current decided with ISET resistance flow.
Next, When it is selected at PWM=L, LED current stop to flow.

LED current setting range
LED current can set up Normal current by resistance value (RISET) connecting to ISET voltage.
Setting of each LED current is given as shown below.

RISET = 720/ILEDmax
Also, Normal current setting range is 10mA~30mA. LED current becomes a leak current MAX 2µA at OFF setting.

● PWM dimming

Current driver PWM control is controlled by providing PWM signal to PWM port, as it is show in Fig. 26. The current set up with ISET is chosen as the H section of PWM and the current is off as the L section. Therefore, the average LED current is increasing in proportion to duty cycle of PWM signal. This method that it lets internal circuit and DC/DC to work, because it becomes to switch the driver, the current tolerance is a few when the PWM brightness is adjusted, it makes it possible to brightness control until 5µs (Min 0.1% at 200Hz). And, don't use for the brightness control, because effect of ISET changeover is big under 1µs ON time and under 1µs OFF time. Typical PWM frequency is 100Hz~25kHz.

![PWM sequence](image1)

**Fig. 26 PWM sequence**

Conditions: 8serial 6parallel, LED current=20mA/ch, VIN=7V, Ta=25℃, Output capacitor=2.2μF(50V/B3)

● Analog dimming

BD6142 control LED current according analog input (ABC terminal).
For ABC voltage = typ 0.733V, LED current can set up Normal current by resistance value (RISET) connecting to ISET voltage.
To decrease ABC voltage, LED current decrease, and to increase ABC voltage, LED current increase.

Please set max LED current to check LED current setting range of P.12 Please care that ABC voltage of max LED current is 0.733V ABC input range is 0.05V~0.9V(Target). This dimming is effected by ISET tolerance as follows.

When you don’t use analog dimming, please set condenser to ABC terminal. Until the condenser of ABC terminal is finished to charge, LED current increase with that speed. The resistor between 1.2V and ABC terminal is 120.9kΩ. Please select the capacitor to care charge time.

**Fig. 29 ILED vs ABC voltage**
Coil selection
The DC/DC is designed by more than 4.7µH. When L value sets to a lower value, it is possibility that the specific sub-harmonic oscillation of current mode DC / DC will be happened. Please do not let L value to 3.3µH or below.
And, L value increases, the phase margin of DC / DC becomes to zero. Please enlarge the output capacitor value when you increase L value. Please select lower DC resistance (DCR) type, efficiency still relies on the DCR of Inductor.
Please estimate Peak Current of Coil. Peak current can be calculated as following.

Peak Current calculation

Peak Current calculation

The estimate of the current value which need for the normal operation
As over current detector of this IC is detected the peak current, it have to estimate peak current to flow to the coil by operating condition.
In case of,
- Supply voltage of coil = Vin
- Inductance value of coil = L
- Switching frequency = fsw (Min=1.0MHz, Typ = 1.25MHz, Max = 1.5MHz)
- Output voltage = VOUT
- Total LED current = ILED
- Average current of coil = Iave
- Peak current of coil = Ipeak
- Cycle of Switching = T
- Efficiency = eff (Please set up having margin)
- ON time of switching transistor = Ton
- ON Duty = D

CCM:  Ipeak = (Vin / L) × (1 / fsw) × (1-( Vin / VOUT))
DCM:  Ipeak = (Vin / L) ×Ton
Iave=( VOUT × IOUT / Vin) / eff
Ton=(Iave × (1- Vin / VOUT) × (1/fsw) × (L/ Vin) × 2)1/2

Each current is calculated.
As peak current varies according to whether there is the direct current superposed, the next is decided.
CCM:  (1- Vin / VOUT) × (1/fsw) <Ton  →  peak current = Ipeak / 2 + Iave
DCM:  (1- Vin / VOUT) × (1/fsw) >Ton  →  peak current = Vin / L × Ton

(Example 1)
In case of, Vin = 7.0V, L = 10µH, fsw = 1.2MHz, VOUT = 32V, ILED = 120mA, Efficiency = 88%
Iave = (32 × 120m / 7) / 88% = 0.62A
Ton = (0.62 × (1 - 7 / 32) × (1 / 1.2M) × (10µ / 7) × 2)1/2 = 1.07µs
(1- Vin / VOUT) × (1/fsw) = 0.65µs < Ton(1.07µs)  CCM
Ipeak = (7 / 10µ) × (1 / 1.2M) × (1 - (7 / 32)) = 0.46A
Peak current = 0.46A / 2 + 0.62A = 0.85A

(Example 2)
In case of, Vin = 16.0V, L = 10µH, fsw = 1.2MHz, VOUT = 32V, ILED = 120mA, Efficiency = 88%
Iave = (32 × 120m / 16.0) / 88% = 0.27A
Ton = (0.27 × (1-16 / 32) × (1 / 1.2M) × (10µ / 16) × 2)1/2 = 0.37µs
(1- Vin / VOUT) × (1/fsw) = 0.41µs > Ton(0.37µs) DCM
Ipeak = Vin / L × Ton = 16 / 10µ × 0.37µs = 0.59A
Peak current = 0.59A

*When too large current is set, output overshoot is caused, be careful enough because it is led to break down of the IC in case of the worst.

DCM/CCM calculation
Discontinuous Condition Mode (DCM) and Continuous Condition Mode (CCM) are calculated as following.

CCM:  L > VOUT × D × (1 - D)² × T / (2 × ILED)
DCM:  L < VOUT × D × (1 - D)² × T / (2 × ILED)

*(Example 1)
In case of, Vin = 7.0V, L = 10µH, fsw = 1.2MHz, VOUT = 32V, ILED = 120mA
VOUT × D × (1 - D)² × T / (2 × ILED) = 32 × (1 - 7 / 32) × (7 / 32)² × 1/(1.2 × 10⁶) / (2 × 0.12) = 4.15µ < L(10µH)  CCM

(Example 2)
In case of, Vin = 12.0V, L = 10µH, fsw = 1.2MHz, VOUT = 32V, ILED = 60mA
VOUT × D × (1 - D)² × T / (2 × ILED) = 32 × (1 - 12 / 32) × (12 / 32)² × 1/(1.2 × 10⁶) / (2 × 0.06) = 19.5µ > L(10µH)  DCM
**OUTPUT Capacitor selection**

Output Capacitor smoothly keeps output voltage and supplies LED current. Output Voltage consists of Charge (FET ON) and Discharge (LED current). So Output voltage has Output ripple Voltage every FET switching.

Output ripple voltage is calculated as following.

- Switching cycle = T
- Total LED current = ILED
- Switching ON duty = D
- Output ripple Voltage = Vripple
- Output Capacitor = COUT
- Output Capacitor (real value) = Creal
- Decreasing ratio of Capacitor = Cerror

\[
C_{\text{real}} = C_{\text{OUT}} \times C_{\text{error}} \quad \text{(Capacitor value is decreased by Bias, so)}
\]

\[
C_{\text{real}} = ILED \times (1-D) \times T / V_\text{ripple}
\]

\[
C_{\text{OUT}} = ILED \times (1-D) \times T / V_\text{ripple} / C_{\text{error}}
\]

(Example 1)

In case of, \(V_{IN}=12.0\)V, \(f_{sw}=1.2\)MHz, \(V_{OUT}=32\)V, \(I_{LED}=120\)mA, \(C_{OUT}=8.8\)µF, \(C_{error}=50\%\)

\[
T = 1 / 1.2\text{MHz}
\]

\[
D = 1 - V_{IN} / V_{OUT} = 1 - 12/32
\]

\[
V_{\text{ripple}} = ILED \times (1-D) \times T / (C_{OUT} \times C_{error}) = 120\text{mA} \times (12/32) / 1.2\text{MHz} / (8.8\text{µF} \times 0.5)
\]

\[
= 8.5\text{mV}
\]

---

![Fig. 30 Bias Characteristics of Capacitor](image-url)
The separations of the IC Power supply and coil Power supply

This IC can work in separating the power source in both IC power supply and coil power supply. With this application, it can obtain that decrease of IC power consumption, and the applied voltage exceeds IC rating 27V.

That application is shown in below Fig.31. The higher voltage source is applied to the power source of coil that is connected from an adapter etc. Next, the IC power supply is connected with a different coil power supply. Under the conditions for inputting from 4.2V to 5.5V into IC VIN, please follow the recommend design in Fig.31. It connects VIN terminal and VDC terminal together at IC outside.

When the coil power supply is applied, it is no any problem even though IC power supply is the state of 0V. Although IC power supply is set to 0V, pull-down resistance is arranged for the power off which cuts off the leak route from coil power supply in IC inside, the leak route is cut off. And, there is no power on-off sequence of coil power supply and IC power supply.

Separate VIN and Coil power supply

Connect VIN and VDC terminals

Fig. 31 Application at the time of power supply isolation
● Layout

In order to make the most of the performance of this IC, its PCB layout is very important. Characteristics such as efficiency and ripple and the likes change greatly with layout patterns, which please note carefully.

<Input bypath capacitor CIN (10μF)>
Put input bypath capacitor CIN (10μF) as close as possible between coil L1 and PGND pin.

<Smoothing capacitor CVDC1(2.2μF) of the regulator>
Connect smoothing capacitor CVDC1(2.2μF) as close as possible between VDC pin and GND.

<Schottky barrier diode SBD>
Connect schottky barrier diode SBD as close as possible between coil L1 and SW pin.

<Output capacitor COUT1>
Connect output capacitor COUT1 between cathode of SBD and PGND. Make both PGND sides of CVIN and COUT1 as close as possible.

<LED current setting resistor RISET(36kΩ)>
Connect LED current setting resistor RISET (36kΩ) as close as possible between ISET pin and GND.

There is possibility to oscillate when capacity is added to ISET terminal, so pay attention that capacity isn’t added.

<Analog dimming pin smoothing capacitor CABC (1nF)>
Put analog dimming pin smoothing capacitor CABC (1nF) close to ABC pin and do not extend the wiring to prevent noise increasing and also LED current waving.

<Frequency setting resistor(56kΩ)>
Put frequency setting resistor(56kΩ) as close as possible between FSET pin and GND.

<Over voltage limit setting resistor ROVP1(2.2MΩ) and ROVP2(68kΩ)>
Put over voltage limit setting resistor ROVP1 (2.2MΩ) and ROVP2 (68kΩ) as close as possible to OVP pin and do not extend the wiring to prevent noise increasing and also detecting over voltage protection in error.

<GMAMP setting resistor RCMP(1kΩ) and CCMP(22nF) for phase compensation>
Put GMAMP setting resistor RCMP (1kΩ) and CCMP (22nF) as close as possible to COMP pin and do not extend the wiring to prevent noise increasing and also oscillating.

<Connect to GND and PGND>
GND is analog ground, and PGND is power ground. PGND might cause a lot of noise due to the coil current of PGND. Try to connect with analog ground, after smoothing with input bypath capacitor CVIN and output capacitor COUT1.

<Heat radiation of back side PAD>
PAD is used for improving the efficiency of IC heat radiation. Solder PAD to GND pin (analog ground). Moreover, connect ground plane of board using via as shown in the patterns of next page.

The efficiency of heat radiation improves according to the area of ground plane.

<Others>
When those pins are not connected directly near the chip, influence is give to the performance of BD6142AMUV, and may limit the current drive performance. As for the wire to the inductor, make its resistance component small so as to reduce electric power consumption and increase the entire efficiency.

The coil is the part that is most influential to efficiency. Select the coil whose direct current resistor (DCR) and current - inductance characteristic is excellent. BD6142A is designed for the inductance value of 10µH. Don't use the inductance value less than 3.3µH. Select a capacitor of ceramic type with excellent frequency and temperature characteristics. Further, select Capacitor to be used with small direct current resistance.

**About heat loss**

In heat design, operate the DC/DC converter in the following condition.

(The following temperature is a guarantee temperature, so consider the margin.)

1. Ambient temperature $T_a$ must be less than 85°C.
2. The loss of IC must be less than dissipation $P_d$. 
1. ESD & Flicker (wakeup (duty 5%@200Hz))
   LED current: 20mA (ISET = 36kΩ)
   LED: 10 LEDs in series, 3 strings in parallel

2. Analog Dimming and monitoring FAULT terminal

- LED current: 20mA (ISET = 36kΩ)
- LED: 10 LEDs in series, 8 strings in parallel

Fig. 39 Application example of Analog dimming
## Notes for use

1. **Absolute Maximum Ratings**
   
   An excess in the absolute maximum ratings, such as supply voltage, temperature range of operating conditions, etc., can break down devices, thus making impossible to identify breaking mode such as a short circuit or an open circuit. If any special mode exceeding the absolute maximum ratings is assumed, consideration should be given to take physical safety measures including the use of fuses, etc.

2. **Operating conditions**
   
   These conditions represent a range within which characteristics can be provided approximately as expected. The electrical characteristics are guaranteed under the conditions of each parameter.

3. **Reverse connection of power supply connector**
   
   The reverse connection of power supply connector can break down ICs. Take protective measures against the breakdown due to the reverse connection, such as mounting an external diode between the power supply and the IC’s power supply terminal.

4. **Power supply line**
   
   Design PCB pattern to provide low impedance for the wiring between the power supply and the GND lines. In this regard, for the digital block power supply and the analog block power supply, even though these power supplies has the same level of potential, separate the power supply pattern for the digital block from that for the analog block, thus suppressing the diffraction of digital noises to the analog block power supply resulting from impedance common to the wiring patterns. For the GND line, give consideration to design the patterns in a similar manner. Furthermore, for all power supply terminals to ICs, mount a capacitor between the power supply and the GND terminal. At the same time, in order to use an electrolytic capacitor, thoroughly check to be sure the characteristics of the capacitor to be used present no problem including the occurrence of capacity dropout at a low temperature, thus determining the constant.

5. **GND voltage**
   
   Make setting of the potential of the GND terminal so that it will be maintained at the minimum in any operating state. Furthermore, check to be sure no terminals are at a potential lower than the GND voltage including an actual electric transient.

6. **Short circuit between terminals and erroneous mounting**
   
   In order to mount ICs on a set PCB, pay thorough attention to the direction and offset of the ICs. Erroneous mounting can break down the ICs. Furthermore, if a short circuit occurs due to foreign matters entering between terminals or between the terminal and the power supply or the GND terminal, the ICs can break down.

7. **Operation in strong electromagnetic field**
   
   Be noted that using ICs in the strong electromagnetic field can malfunction them.

8. **Inspection with set PCB**
   
   On the inspection with the set PCB, if a capacitor is connected to a low-impedance IC terminal, the IC can suffer stress. Therefore, be sure to discharge from the set PCB by each process. Furthermore, in order to mount or dismount the set PCB to/from the jig for the inspection process, be sure to turn OFF the power supply and then mount the set PCB to the jig. After the completion of the inspection, be sure to turn OFF the power supply and then dismount it from the jig. In addition, for protection against static electricity, establish a ground for the assembly process and pay thorough attention to the transportation and the storage of the set PCB.

9. **Input terminals**
   
   In terms of the construction of IC, parasitic elements are inevitably formed in relation to potential. The operation of the parasitic element can cause interference with circuit operation, thus resulting in a malfunction and then breakdown of the input terminal. Therefore, pay thorough attention not to handle the input terminals, such as to apply to the input terminals a voltage lower than the GND respectively, so that any parasitic element will operate. Furthermore, do not apply a voltage to the input terminals when no power supply voltage is applied to the IC. In addition, even if the power supply voltage is applied, apply to the input terminals a voltage lower than the power supply voltage or within the guaranteed value of electrical characteristics.

10. **Ground wiring pattern**
    
    If small-signal GND and large-current GND are provided, It will be recommended to separate the large-current GND pattern from the small-signal GND pattern and establish a single ground at the reference point of the set PCB so that resistance to the wiring pattern and voltage fluctuations due to a large current will cause no fluctuations in voltages of the small-signal GND. Pay attention not to cause fluctuations in the GND wiring pattern of external parts as well.

11. **External capacitor**
    
    In order to use a ceramic capacitor as the external capacitor, determine the constant with consideration given to a degradation in the nominal capacitance due to DC bias and changes in the capacitance due to temperature, etc.

12. **Thermal shutdown circuit (TSD)**
    
    When junction temperatures become 130°C (typ) or higher, the thermal shutdown circuit operates and turns a switch OFF. The thermal shutdown circuit, which is aimed at isolating the LSI from thermal runaway as much as possible, is not aimed at the protection or guarantee of the LSI. Therefore, do not continuously use the LSI with this circuit operating or use the LSI assuming its operation.

13. **Thermal design**
    
    Perform thermal design in which there are adequate margins by taking into account the permissible dissipation (Pd) in actual states of use.

14. **Selection of coil**
    
    Select the low DCR inductors to decrease power loss for DC/DC converter.

The Products specified in this document are intended to be used with general-use electronic equipment or devices (such as audio visual equipment, office-automation equipment, communication devices, electronic appliances and amusement devices).

The Products specified in this document are not designed to be radiation tolerant.

While ROHM always makes efforts to enhance the quality and reliability of its Products, a Product may fail or malfunction for a variety of reasons.

Please be sure to implement in your equipment using the Products safety measures to guard against the possibility of physical injury, fire or any other damage caused in the event of the failure of any Product, such as derating, redundancy, fire control and fail-safe designs. ROHM shall bear no responsibility whatsoever for your use of any Product outside of the prescribed scope or not in accordance with the instruction manual.

The Products are not designed or manufactured to be used with any equipment, device or system which requires an extremely high level of reliability the failure or malfunction of which may result in a direct threat to human life or create a risk of human injury (such as a medical instrument, transportation equipment, aerospace machinery, nuclear-reactor controller, fuel-controller or other safety device). ROHM shall bear no responsibility in any way for use of any of the Products for the above special purposes. If a Product is intended to be used for any such special purpose, please contact a ROHM sales representative before purchasing.

If you intend to export or ship overseas any Product or technology specified herein that may be controlled under the Foreign Exchange and the Foreign Trade Law, you will be required to obtain a license or permit under the Law.
